Open Thesis (BA, MA, SA)

Mathematical modeling and analysis of apoptosis in cell populations

Field of Research:
Apoptosis is a mechanism of programmed cell death, important for instance in developmental processes of organisms. A promising alternative to the mechanisms of common therapies against cancer is the activation of death receptors with help of TRAIL. Experimental data are rather obtained from cell populations than from measurements of single cells. The modeling of cell populations is a challenging task because of a high heterogeneity within the population. Intrinsic and extrinsic noise of cells can be considered for example by use of stochastic modeling methods. Together with cooperation partners on the experimental side we are interested in understanding the apoptotic response and resistance mechanisms in different cancer cell lines. One longterm goal is to obtain a holistic multi-scale model of the effects of a therapy with TRAIL and to reveal the constraints for maximal therapy efficiency. A student thesis is possible in this field. The exact topic and goal can be determined in a personal discussion.

Prerequisites:
- Basic knowledge in biochemistry and molecular biology
- Knowledge in systems biology and modeling
- Skills in Matlab or Python

Supervisor:
Dirke Imig
Room 3.241

Area:
Systems Biology

Properties:
Type: BA, MA, SA
30% literature
40% implementation
30% simulation

Beginning:
Now
